# Software Quality

# Motivating Examples: Major

- 1985–1987 – *Therac-25*:
  - Radiation therapy overdose
  - Control software flaw:
    - Race conditions
  - Death of 6 (six) cancer patients
- 1996 – *Ariane-5 missile*:
  - Missile crash
  - Control software flaw:
    - 64-bit float to 16-bit int
  - \$7 billion development program
  - \$500 million cargo
- 2005 – *Toyota Camry*:
  - Sudden unintended acceleration:
  - Control software flaw:
    - Recursion causing stack overflow
  - 89 deaths and 57 injuries
  - \$1.2 billion compensations

Verification  
Examples

Concluding  
remarks

Is formally defined in, e.g.: ISO-9000:2015:

- **Verification** – *“Confirmation, through the provision of objective evidence, that specified requirements have been fulfilled.”*
- **Validation** – *“Confirmation, through the provision of objective evidence, that the requirements for a specific intended use or application have been fulfilled.”*

# Software Development: Testing

- **Verification:**
  - Are we building the product right?
  - Does the system comply with its specification?
- **Validation:**
  - Are we building the right product?
  - Does the system meet the needs of the customer?

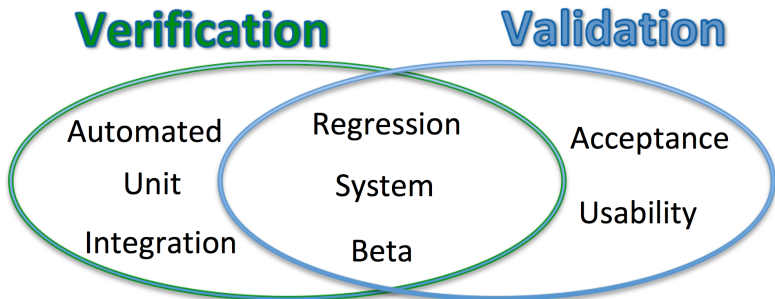

Figure 2: Devision of testing types

# Formal Verification

## Facts:

- No globally recognized definition of Formal Methods<sup>1</sup>.
- Local attempts to have one<sup>2</sup>, e.g.:

*Formal methods are techniques used to model complex systems as mathematical entities.*

*By building a rigorous model of a complex system, it is possible to verify the system's properties in a more thorough fashion than empirical testing.*

## Conclusion:

Formal methods are techniques suitable for Verification.

# Software Verification

## Goal:

A program shall satisfy a formal specification of its behavior.

# Programming Languages

# Language generations

Figure 4: Generations of Programming languages

# Declarative vs. Imperative: Main

- *Declarative* – Expresses what to accomplish without specifying concrete steps.

```
//Declarative `JavaScript`  
var arr_dbl = arr.map((x) => x * 2)
```

- *Imperative* – Describes computation in terms of statements that change a program state.

```
//Imperative `JavaScript`  
var arr_dbl = []  
for (let i = 0; i < arr.length; i++) {  
    arr_dbl.push(arr[i] * 2)  
}
```

# ANSI-C: Just an old C

## Procedural language:

Is an imperative language in which the program is built from one or more subroutines commonly known as `functions`.

## C language:

C is an *imperative procedural* language.

## ANSI-C:

ANSI-C is a common name for two equivalent language specs:

- C89 by American National Standards Institute (ANSI)
- C90 by International Organization for Standardization (ISO)

# Formal Methods

# Formal verification

**Question:** Does formal *validation* exist?

Figure 6: Formal correctness proving

*Prove* conformance to specifications for *imperative programs*.

## Hoare Approach<sup>3</sup>

**Hoare triples:**  $\{P\} C \{Q\}$

$C$  - code;  $P$  - pre-condition;  $Q$  - post-condition;

**Axioms**, e.g. *Skip* and *Assign*:

$$\overline{\{P\} \text{skip} \{P\}} \text{ and } \overline{\{P[E/V]\} V := E \{P\}}$$

Where  $E$  is any expression and  $V$  is any variable.

**Inference rules**, e.g. *Composition* and *Conditional*:

$$\frac{\{P\} S_1 \{R\}, \{R\} S_2 \{Q\}}{\{P\} S_1; S_2 \{Q\}} \text{ and } \frac{\{B \wedge P\} S \{Q\}, \{\neg B \wedge P\} T \{Q\}}{\{P\} \text{ if } B \text{ then } S \text{ else } T \text{ elseif } \{Q\}}$$

**Partial correctness:** If  $P$  holds before executing  $C$  then  $Q$  holds afterwards, **ONLY** if  $C$  terminates.

---

<sup>3</sup>"An Axiomatic Basis for Computer Programming", Tony Hoare, 1969.

# Edsger Dijkstra<sup>4</sup>

The *weakest precondition calculus* for

- A predicate transform semantics to mechanize the proofs.
- Explains how  $C$  transforms  $P$  into  $Q$ .

## Backward reasoning:

- Based on  $Q$  and  $C$  calculate the *weakest pre-condition*  $\hat{P}$
- If  $P \implies \hat{P}$ , then the proof is complete

## Forward reasoning:

- Based on  $P$  and  $C$  calculate the *strongest post-condition*  $\hat{Q}$
- If  $\hat{Q} \implies Q$ , then the proof is complete

Concluding  
remarks

# Frama - C

# Platform description

A plug-in-based open-source cross-platform framework for C source-code analysis:

- Browsing unfamiliar code
- Static code analysis
- Dynamic code analysis
- Code transformations
- Certification of critical software

You can easily build upon the existing plug-ins to implement your own analysis.

# Plugins overview: Main

# What is ACSL: General

In short:

- ACSL – ANSI/ISO C Specification Language
- Allows to formally specify properties of a C program

It is all about function contracts:

```
/*@ ensures \result >= x && \result >= y;  
    ensures \result == x || \result == y;  
*/  
int max (int x, int y) {  
    return(x > y) ? x : y;  
}
```

A function contract is a combination of:

- post-conditions - ensures
- pre-conditions - requires

# What is ACSL: Pointers

ACSL allows to reason about, e.g.:

- Pointers
- Arrays
- Termination

Consider pointers:

```
/*@ requires \valid(p) && \valid(q);  
    ensures *p <= *q;  
    */  
void max_ptr (int *x, int *y) {  
    if(*x > *y) {  
        int tmp = *x;  
        *x = *y;  
        *y = tmp;  
    }  
}
```

# What is ACSL: Completeness

Is the following `max_ptr` implementation correct?

```
/*@ requires \valid(p) && \valid(q);
    ensures *p <= *q;
*/
void max_ptr (int *x, int *y) {
    *p = *q = 0;
}
```

Is the following specification *complete*?

```
/*@ requires \valid(p) && \valid(q);
    ensures *p <= *q;
    ensures (*p == \old(*p) && *q == \old(*q)) ||
           (*p == \old(*q) && *q == \old(*p));
*/
void max_ptr(int*p, int*q);
```

## What is ACSL: The spec.

The complete specification v1.4 has 93 pages:
